The **LEFT OUTER JOIN** or simply **LEFT JOIN** (you can omit the OUTER keyword in most databases), selects all the rows from the first table listed after the FROM clause, no matter if they have matches in the second table.

If we slightly modify our last SQL statement to:

```
SELECT Customers.Name, SUM(Sales.Sale_Amount) AS
Sales_Per_Customer
FROM Customers LEFT JOIN Sales
ON Customers.Customer_ID = Sales.Customer_ID
GROUP BY Customers.First_Name, Customers.Last_Name
```

and the Sales table still has the following rows:

Customer_ID	Date	Sale_Amount
2	5/6/2004	$100.22
1	5/6/2004	$99.95

The result will be the following:

Name	Sales_Per_Customers
John	$99.95
Steven	$100.22
Paula	NULL
James	NULL

```
create table customers
(
   Customer_ID    integer primary key,
   Name           varchar2(20)
);

create table sales
(
   Sale_ID        integer primary key,
   Customer_ID    integer,
   Sale_Date      date,
   Sale_Amount    integer
);

insert into customers values (1, 'Luke');
insert into customers values (2, 'Hong');
insert into customers values (3, 'Candice');
insert into customers values (4, 'Natalie');

insert into sales values (1, 1, to_date('2003/07/08', 'yyyy/mm/dd'), 11);
insert into sales values (2, 1, to_date('2003/07/09', 'yyyy/mm/dd'), 12);
insert into sales values (3, 2, to_date('2003/08/08', 'yyyy/mm/dd'), 22);
insert into sales values (4, 2, to_date('2003/08/09', 'yyyy/mm/dd'), 33);

select c.name, sum(s.sale_amount)
from customers c left join sales s
on c.Customer_Id = s.Customer_Id
group by c.name
order by c.name;

select c.name, sum(s.sale_amount)
from customers c, sales s
where c.Customer_Id = s.Customer_Id(+)
group by c.name
order by c.name;

/
