

Hibernate Association O/R Mapping				
	Unidirectional		Bidirectional	
	Foreign Key	Join Table	Foreign Key	Join Table
many to one	Most common	Quite common when the association is optional	Most common. This is the standard parent/child relationship.	
one to one	Most common	Extremely unusual	Quite common	Extremely unusual
one to many	Very unusual case. Not really recommended. It's better to use a join table for this kind of association.	Much more preferred than through foreign key		
many to many				

1. In a bidirectional relationship, one of the sides (and only one) has to be the owner: the owner is responsible for the association column(s) update. To declare a side as not responsible for the relationship, the attribute mappedBy is used. mappedBy refers to the property name of the association on the owner side.
2. If no @JoinColumn is declared on the owner side, the defaults apply. A join column(s) will be created in the owner table and its name will be the concatenation of the name of the relationship in the owner side, _ (underscore), and the name of the primary key column(s) in the owned side.
